PASHMINA INTELLIGENCE · METHOD NOTE

How we calculate the numbers

Snapshot 27 Oct 2026 · India · for the dashboard at 01adityarathore-art.github.io/pashmina-intel-view

Every verdict compares a design or colour with **its own normal**: the same account's usual likes, the same store's usual sell-out rate, the category's usual search growth. A big brand or a viral post can't win on size alone, and small samples are pulled toward average before anything is judged.

L1
Search demand
How many people search Google for shawls and pashmina, and when

L2
Search intents
The same searches split by what people typed

L3
Designs & colours
Do buyers act on it? Do sellers push it?

L4
Evidence
Every query, piece, post and video behind a number

1 · Where the data comes from

SOURCE	WHAT WE TOOK	VOLUME	COST
Google search (DataForSEO: Google Ads + Labs)	Monthly searches in India for every shawl and pashmina query, 26 months	6,136 queries	$0.41
32 seller websites (Shopify catalogues)	Each piece's title, price, in stock or sold out, launch date	12,659 pieces · 3,347 sold out	free
Instagram via DuckDuckGo and Google results	Post likes and comments (Instagram's own API gives none)	1,631 posts	436 SerpApi searches
Instagram accounts (SerpApi)	What 91 accounts posted recently	857 posts	
YouTube Data API (your free key)	Views, likes, comments, channel country	559 videos · 44.8M views	free
Google Trends, autocomplete, Shopping, Amazon	Season shape, states, rising questions, mass-market prices and "bought in past month"	1,054 listings	in the 436

Posts and videos from Pakistan, Bangladesh, the Gulf and Indonesia are removed, as are sarees, suits, kurtas and abayas that only mention a shawl.

L1 Search demand

Google reports close variants of a query with **one shared number**. Adding raw rows counts the same people many times (the raw total is a meaningless 3.9 million), so variants are first merged into **demand pools**: queries with the same 12-month pattern and the same words once spelling, plurals and synonyms (women = ladies = woman) are evened out. Only pools are added up.

> **Example.** "pashmina shawl", "shawl pashmina", "pashmina woolen shawl", "pashma shawls" and 5 more all show 90,500 a month. They are one pool, counted once: 90,500, not 9 × 90,500.

- **Volume** = average monthly searches over the last 12 months.
- **Growth** = last 3 months ÷ the same 3 months a year earlier − 1. Three months smooth Google's rounding.
- **Removed as noise:** a Class 6 English chapter called "The Kashmiri Shawl", the actress Pashmina Roshan, apartment projects named Pashmina, knitting patterns.

Result: **1.15M** shawl searches a month; **421K** are pashmina or Kashmiri (37%), up **85%**, peaking in December.

L2 Search intents

Each pool goes into the **first** intent it matches, in this order, so every search is counted exactly once and the shares add up to 100%:

`Is it real` → `Price` → `Where to buy` → `Brand` → `Design` → `Colour` → `Occasion & gift` → `Men` → `Women` → `Stoles & scarves` → `Learn & care` → otherwise `Just browsing`

> **Example.** "pure pashmina shawl price" mentions both purity and price; it lands in **Is it real** because that comes first. "Is it real" totals 27,460 a month = 6.5% of pashmina searches, +97% vs last year. **Cost per click** is what advertisers pay Google for that click, weighted by volume.

L3 Buyer pull: what buyers do

Each signal is a ratio where **1.00× means normal**:

SIGNAL	HOW IT'S WORKED OUT
Instagram likes	Each post's likes ÷ that account's usual likes (median of its 3+ posts; otherwise the typical post or reel). Averaged on a log scale per account, then across accounts.
Sells out	Pieces of the design that sold out ÷ how many would have, at each store's own sell-out rate.

SIGNAL	HOW IT'S WORKED OUT
YouTube views	Each video's views ÷ the typical video that names a design. Averaged per channel.
Amazon pull	Share of "bought in past month" ÷ share of listings. Mass tier only, as Amazon is mostly imitation pashmina.

Then two safety steps:

- **Pulled toward average:** `adjusted = ratio ^ (n ÷ (n + k))`. With few posts or pieces (small n) the ratio moves toward 1.00×.
- **Capped** between 0.4× and 2.5×, so no single signal can decide alone.

Buyer pull = the geometric mean of the signals that have enough data.

Seller push

The design's share of Instagram posts and website listings that name a design (an average of the two). **New launches** = its share of pieces launched in the last 120 days and posts from the last 60 days ÷ its share before that.

Verdicts

VERDICT	RULE
Stock now	Buyer pull ≥ 1.12× and seller push at or above the tier's median
Early bet	Buyer pull ≥ 1.12× but seller push below the median: wanted, few sell it
Crowded	Buyer pull ≤ 0.89× and push at or above the median (or launches growing ≥ 1.15×)
Skip	Buyer pull ≤ 0.89× and little push
Hold	Everything in between (within ±12% of normal)

Kalamkari, luxury tier → Stock now. 167 of 405 pieces sold out = 1.32× its stores' usual rate → adjusted for sample size 1.30×. Seller push is 13.5%, above the luxury median of 3.6%, so the verdict is Stock now (median price ₹1.75L).

Kani, all buyers → Crowded. Likes 0.96× (159 accounts) · YouTube 0.72× → 0.75× (32 channels) · sell-out 0.95× (2,055 pieces) → buyer pull = $(0.96 \times 0.75 \times 0.95)^{1/3}$ = 0.88×. Seller push is 24.8%, far above the 7.3% median, so the verdict is Crowded, even though Kani is the most-searched design (13.8K a month).

Tiers come from real prices: Mass under ₹5,000, Mid ₹5,000–25,000, Luxury ₹25,000+. USD and EUR stores are converted at approximate rates (₹88, ₹101).

Trend Lab: what is trending now

Five signals, each against normal, adjusted and capped as above, then log-averaged into a **trend score**:

1. Share of this month's posts (last 30 days) ÷ share in the 5 months before
2. Likes vs each account's usual, this month
3. Share of launches in the last 60 days ÷ share among older pieces at the same stores
4. Google growth ÷ the category's growth: (1 + colour growth) ÷ (1 + 85%)
5. Sell-out vs its store

Hot ≥ 1.25× · **Rising** ≥ 1.08× · **Steady** · **Cooling** ≤ 0.90× · fewer than 3 signals = **Thin data**. "Driven by" names only the signals pushing in the verdict's direction.

> **Maroon → Rising (1.15×).** Post share 0.96× → 0.97 · likes 3.88× → 2.41 (11 posts) · launches 0.64× → 0.68 · Google +147% vs category +85% → 1.34 · sell-out 0.96× → 0.96 · score = $(0.97 \times 2.41 \times 0.68 \times 1.34 \times 0.96)^{1/5}$ = 1.15×. Buyers love maroon on Instagram and search it more, but sellers are launching less of it: a gap.

The other tabs

- **Stock these:** design + colour pairs that sell out more than their stores' other pieces at 2+ stores, ranked by that lift × the design's buyer pull. The price shown is the middle half of the pieces that actually sold out.
- **Opportunity matrix:** the same sell-out lift for every design × colour pair. "White space" = 1.2×+ lift, 3+ sold, few listed. *Example: Aari in navy: 7 of 35 sold out at 10 stores = 1.63×.*
- **Launch radar:** pieces with a publish date in the last 30 days (1,067).
- **Content playbook:** 451 posts from 87 accounts with 3+ posts, each vs its own account's usual likes. Posts with a feature vs without it. *Example: reels 1.60× vs photos.*
- **Price ladder:** 10th, 25th, 50th, 75th and 90th percentile of listed prices.

Limits

- Likes come from posts that search engines show; most carry no price, so Luxury and Mid verdicts rest mainly on sell-outs.
- "Sold out" can also mean discontinued; comparing within each store limits that. Big stores show only their newest 1,000 pieces.
- Designs and colours are read from titles, captions and tags. A photo check matched well for Kalamkari, Sozni, Jamawar and Ikat.
- Google rounds volumes into buckets, so small queries move in steps.
- This is the first snapshot; week-on-week change starts with the next refresh (≈195 SerpApi searches; Google volumes reused for 25 days).
